Safety Analysis of Dorsal Root Ganglion Stimulation in the Treatment of Chronic Pain

Timothy Deer, MD*; Jason Pope, MD†; Corey Hunter, MD‡; Steven Falowski, MD§; Leonardo Kapural, MD, PhD¶; Jeffery Kramer, PhD**; Robert Levy, MD, PhD††‡‡

**Background:** Stimulation of the dorsal root ganglion (DRG) in the treatment of chronic, intractable pain has shown excellent clinical results in multiple published studies, including a large prospective, randomized, controlled trial. Both safety and efficacy have been demonstrated utilizing this therapeutic approach for many chronic complaints. Continued assessment of neuromodulation therapies, such as DRG stimulation, are not only an important aspect of vigilant care, but are also necessary for the evaluation for safety.

**Materials and Methods:** Safety and complaint records for DRG and spinal cord stimulation (SCS) stimulation were obtained from the manufacturer, analyzed and compiled to further assess ongoing device safety. Complaint event data were stratified according to complain type as well as overall rates. Data from similar time periods were compared between epidural neurostimulation devices by the same manufacturer as well as rates reported in the literature.

**Results:** Overall, DRG stimulation device event rates were lower or comparable to similar epidurally placed neurostimulation devices. Rates of events varied from 0 to 1.0% for DRG stimulation (n >500+ implants) which was similar to the event rate for SCS by the same manufacturer (n >2000+ implants). In comparison, complaints and adverse events ranged from 0 to 14% for SCS in the literature.

**Discussions:** The current results from a large consecutive cohort obtained from manufacturer records indicates that DRG stimulation demonstrates an excellent safety profile. Reported event rates are similar to previously reported adverse event and complaint rates in the literature for this therapy. Similarly, safety events rates were lower or similar to previously reported rates for SCS, further demonstrating the comparative safety of this neuromodulation technique for chronic pain treatment.

**Keywords:** chronic pain, epidural, implant, Neurostimulation, safety

**Conflict of Interest:** Dr. Deer is a consultant for Abbott, Axonics, Nalu, Saluda, Vertos, Vertiflex, Flowonix, and SpineThera, and has funded research from Abbott, Saluda, Vertiflex, and Vertos and Mainstay. He has minority equity in Axonics, Bioness, Ethos, Flowonix, Saluda, Nalu, Cornerloc, Spinethera, Vertos, and Vertiflex. Dr. Pope is a consultant for Abbott, Saluda, VertiFlex, Vertos, SpineThera, Jazz Pharmaceuticals, Flowonix, and SPR Therapeutics, has funded research with Abbott, Flowonix, VertiFlex, Saluda, and has minority equity in AGR, SPR Therapeutics, Celere Health. Dr. Kramer is a consultant for Abbott, Autonomic Technologies, Nalu Medical, Circuit Therapeutics, CereVu and ENSO. Dr. Levy—Abbott (consultant, Medical Advisory Board), Mainstay Medical (consultant, Medical Advisory Board), Nalu (consultant, Medical Advisory Board), Nuvestra (consultant, Medical Advisory Board), Saluda (consultant, Medical Advisory Board). Dr. Falowski is a consultant for Abbott, Medtronic, Nevro, Vertiflex, Saluda, and SPR therapeutics; funded research from Abbott, Medtronic, Nuvestra, Biontrik; has minority equity in SpineThera, SPR therapeutics, Saluda, AGR, and Suture Concepts. Dr. Kapural is consultant for Nevro, Abbott, Best Doctors and has funded research from Biontrik, SPR Therapeutics, Medtronic, Boston Scientific, Neuros, Gimer, Sollis Medical. Dr. Hunter is a consultant for Abbott, Saluda, Nuvestra, Flowonix and serves on the Medical Advisory Board for VertiFlex.

INTRODUCTION

The dorsal root ganglion is a sensory neural structure located within the intervertebral foramen that contains the primary sensory neuron (PSN) somata ([1–3]). Several reviews have outlined the importance that the PSN plays in the development and maintenance of chronic pain ([1,4,5]). Many of the pathophysiologic changes in neuronal function of PSNs observed in models of chronic pain are specifically located in the neuronal cell body, and these can include increased membrane excitability as well as the generation of ectopic action potentials ([1,6–8]). The PSNs also contain a t-junction where the distal and primary axons combine with a stem axon that connects the soma. This junction in the pseudounipolar neurons acts as a junctional failure point for centrally projecting neural traffic. It also serves as a modular area for controlling sensory information originating from both the periphery and cell body to more central neural pathways ([9,10]). Given these functional considerations and the anatomic accessibility of the dorsal root ganglion (DRG) in the spine, neurostimulation techniques have been developed to therapeutically target this spinal structure ([3,11–13]).

Clinically, it has been shown in multiple, published studies that DRG stimulation produces significant analgesia in patients suffering from chronic pain ([11,14–17]). This includes results from a large, prospective, multi-center, randomized controlled trial (ACCURATE study) in which DRG stimulation was shown to be safe and effective ([11]). The ACCURATE study also demonstrated that DRG stimulation is superior to spinal cord stimulation (SCS) in the treatment of CRPS types I and II (causalgia). Subsequent studies have not only shown utility of this neuromodulation target in other pain conditions outside CRPS, but also have continued to document the clinically efficacy and safety of this therapeutic approach in “real-world” settings ([12,14,16,18–21]). After regulatory approvals (both CE Mark and FDA), commercialization of the only product approved for DRG stimulation in the treatment of chronic pain has allowed increased patient access to this important neuromodulation therapy.

One important aspect of medical device use is ongoing safety assessments and vigilance efforts by both physicians and manufacturers. There are multiple ways to adequately assess postmarket safety including running specific postmarket safety studies in large patient populations (often a requirement of device regulatory approval), systematic reviews of peer-reviewed published data, analysis of public safety databases as well as review of manufacturer internal complaint and safety records. Each of these approaches have their strengths and weaknesses ([22]), but given the regulatory requirements for device vigilance reporting, internal company records are generally the most accurate reporting methods for very large cohorts. Quite often, however, these records and results are not made public. Many of these approaches have been used to assess ongoing safety of neuromodulation devices ([12,22–25]) and are synthesized in clinical consensus recommendations, such as those published by the Neuromodulation Appropriate Use Consensus Committee (NACC) ([26–28]).

To assess the ongoing performance and safety of DRG stimulation, we have compiled and analyzed device specific manufacturer safety and complaint records. For comparative purposes, the records analyzed included both DRG and SCS systems from the same manufacturer. Data, generously provided by Abbott Neuromodulation (Chicago, IL, USA), were systematically collected from an internal complaint reporting and handling database and utilized in the current analysis. The product experiences reported and recorded in this type of database are used to collect any written, electronic, or oral communication that alleges deficiencies related to the physical characteristics, identity, quality, purity, potency, durability, reliability, safety, effectiveness, or performance of a distributed product. The time frame selected was April 2016 to March 2018 based on DRG stimulation FDA approval. Comparative safety data were also acquired through a review of the DRG and SCS published literature (data sources: Medline and EMBASE).

The comparison between the two therapies was limited only to products implanted within this time frame to provide a direct comparison of product performance utilizing the same associated implant durations. Data were validated through the manufacturer’s quality assurance system for complaint handling, and both a unique patient identifier as well as specific data fields for device identification and the specific complaint descriptor/category were compiled. The sources of potentially reportable events included, but were not limited to, the following: Customer complaints (primary source), contact with manufacturer employees or contract personnel, field service records, device malfunctions, advertising and promotion materials, professional meetings, congresses, seminars, clinical studies using manufacturer marketed products and clinical research, product actions, legal actions, regulatory affairs, manufacturer employees of different divisions, other companies with manufacturer/distributor relationships with manufacturer, regulatory agencies, and other telecommunications (internet), website postings, web logs (blogs) and published literature. Each of the patient implant records were characterized into groups based on the implantable pulse generator (IPG) and leads that were implanted together. Only implanted systems where both an IPG and a lead were implanted were included for this evaluation. Implant records were excluded from the investigation in rare cases where there were multiple IPGs and leads implanted involving both DRG and SCS devices in the same patient. Records from any associated accessories (eg, lead anchors, lead extensions, etc.) were not included in this analysis.

Based on the implant data records, the “Implant Therapy” was determined based on the IPG model utilized. Products were further grouped into “Implant Family” based on the IPG model (SMI-Axium [DRG] Proclaim DRG or Proclaim SCS) and the implanted lead models (DRG lead, SCS percutaneous lead, SCS surgical/paddle lead). Information (patient ID, model, serial/lot number, implant date) from the patient implant data was used to identify the related complaint records. Once matched, the complaint record details were then associated with the patient implant event and the associated “Implant Therapy” and “Implant Family,” after which the patient implant record was marked to indicate whether there was a complaint and/or explant associated with the implant event. Comparative rates of complaint and explant were calculated using either the “Implant Therapy,” “Implant Family,” individual product model, or specific complaint record variable by summing the number of associated complaints and explant records and normalizing by the number of overall implant records for the “Implant Therapy,” “Implant Family,” or individual product model.

Data were compiled and stratified according to general event categories as has been previously published ([11,25,29]). Event categories ranged from biological/physical descriptor to device events (device malfunction or related events). A literature review was also conducted to retrieve safety reporting from the published literature. Multiple databases (Medline and EMBASE) were searched with...
relevant search terms (“Dorsal root ganglion stimulation,” “DRG stimulation,” “spinal cord stimulation,” “safety,” etc.) in order to produce comparative data from peer-reviewed publications.

RESULTS

Manufacturer records yielded data from over 500 DRG stimulator and 2000 spinal cord stimulator implants. Primary results and outcomes from the manufacturer records are presented in Table 1. Overall, DRG stimulation reported safety event rates were 3.2%. This compares to an event rate during the same time frame of 3.1% in SCS. Infection was the most frequent event noted, with an overall rate of approximately 1% for both DRG and SCS systems. This was one-third of overall event incidence. All other biologically classified event rates were less than 1%. Comparatively, both the DRG and SCS systems demonstrated equivalent event rates from the manufacturer records with slight variations in individual categories. Table 2 lists the comparative incident rates of the highest occurring events (infection, pain at implant site and CSF leaks) in the current data set and literature for both DRG and SCS. In all cases, the incident rates reported in the literature are either higher or the same as reported from the manufacturer records in the current analysis.

Event rates were also comparable or better than the published literature for both SCS and DRG systems. Table 3 shows the manufacturer event rates compared to the event rates reported in the ACCURATE study. The manufacturer postmarket events rates were either comparable or less than the rates reported in the ACCURATE clinical trial demonstrating continued or improved safety of the DRG stimulation system. Results from a literature review demonstrated that the current event rates compared favorably to published SCS clinical event rates.

DISCUSSION

The findings from this safety analysis, including >500 DRG system implants from a 2-year time period following commercial approval, demonstrate that clinical adverse events and device complaint rates were comparably or less frequent than those reported for, 1) similar epidural SCS neurostimulation systems in the literature, 2) similar SCS systems from the same manufacturer in the same time frame as DRG stimulation, 3) a similar DRG system as

Comparison between events reported in current analysis and published rates from SCS and nerve root stimulation.

*Reference (31).
reported in the results from a large, prospective, multi-center, randomized controlled trial (ACCURATE), and, 4) a similar DRG stimulation system as reported in the literature. These findings represent the most complete postmarket safety analysis completed for DRG stimulation and consider all reported events from a manufacturer quality system for commercially implanted systems within a 2-year time frame. This approach helped to avoid biases of event reporting in public databases and also allows for a larger sample size of device reporting than all published clinical studies combined.

The overall incidence rate of 3.2% for DRG stimulation was comparable to the event rate for fully-implantable SCS systems (3.1%) from the same manufacturer and so represents a true comparison of rates given that the same requirements for reporting and methods for data collection were taken as a part of the required device vigilance monitoring. These rates are similar to those observed during the ACCURATE clinical trial conducted for FDA approval as well as those reported in the literature (11,12,15,17,18,30). The latter of these two data collection methods (clinical studies) yield fairly large ranges of events, mostly due to the heterogeneity in data collection methods, reporting decisions and the fact that data was obtained from different geographies as well as different clinical sites. This approach, however, provides event rates from different sources, and in so doing yields data from larger patient samples than available through single clinical studies.

To that extent, the results from the current analysis are also in agreement with event rates published from the ACCURATE study (11). Safety event rates published from large clinical studies are another good source for comparative data. Generally, the events reported from high-quality clinical trials involve smaller and more homogeneous patient populations than larger postmarket patient cohorts. The data is also collected within a highly controlled environment, generally with very experienced physicians participating as investigators. It is very encouraging to see that, in the current analysis, data collected from a “real-world” setting, such as clinical practice across multiple locations and physicians, matches or exceeds the safety rates from controlled clinical studies. Not only do the postmarket results substantiate those findings from the approval study, but also demonstrate increased external validity of the initial safety results within a more varied patient group in variable practice environments. Refined placement techniques and safety considerations, including neuromonitoring and awake

Figure 1. Fluoroscopic images of spine anatomy relating location of the dorsal root ganglia as well as implanted DRG leads in the foramen and SCS lead in the lateral epidural space. Panel A depicts relevant spinal anatomy and location of the DRG within the dorsal aspect of the neural foramen just under the spinal pedicle. Panel B shows a lead specifically designed for DRG stimulation in the dorsal intervertebral foramen adjacent to the DRG. Note the flexibility and outer diameter of the lead. Panel C shows a lead designed for spinal cord stimulation in the lateral epidural space partly extending into the ventral spinal foramen. Note the difference in lead approaches and locations in the lateral recess. [Color figure can be viewed at wileyonlinelibrary.com]
CONCLUSION

Following review and analysis of manufacturer safety records, DRG stimulation continues to demonstrate an excellent safety profile with low adverse event rates. The current analysis has reinforced the initial findings that DRG stimulation demonstrates an excellent safety profile that is equal or better to, 1) the ACCURATE pivotal trial results, 2) SCS devices, 3) results from published literature on both DRG and SCS therapies.

These event rates are also consistent or lower with rates previously deemed acceptable by neuromodulation consensus committees and regulatory agencies. Ongoing device vigilance and safety reporting by physicians will continue to be a valued assessment of the safety and performance attributed to DRG stimulation therapy as well as other neuromodulation approaches.

Authorship Statements

Drs. Deer and Kramer conducted the data analysis and assembly for presentation in the document. Dr. Kramer prepared the manuscript draft with important intellectual input from Drs. Deer, Levy, Falowski, Pope, Kapural, and Hunter. All authors provided editorial input. Abbott provided safety and device diligence data from internal databases for analysis and inclusion in the manuscript.
